

Aortic Dissection Detection Risk Score (ADD-RS)

The ADD-RS rules out aortic dissection.

Calculator Review Author

About the Score

The Aortic Dissection Detection Risk Score (ADD-RS) should be used for low- to moderate-risk patients for whom acute aortic syndromes (AAS) are in the differential diagnosis. This tool, used in combination with a D-dimer test, has been proposed and internally validated as a diagnostic algorithm. There are significant caveats to the tool, including the following:

- The algorithm has not been externally validated.
- Half of the patients included in the original study did not have definitive imaging, and the study limitation of 14 days of follow-up raises the possibility of missed cases.
- The American College of Emergency Physicians' 2014 Clinical Policy on thoracic aortic dissection advises against using D-dimer alone to rule out AAS, though this recommendation is based on Level C evidence.
- ADD-RS and D-dimer are not meant to diagnose AAS, but rather to provide guidance in risk stratifying patients for imaging.

The ADD-RS may reduce misdiagnosis and overtesting for AAS, thereby avoiding unnecessary radiation exposure and the cost associated with definitive imaging. Consider using this risk stratification algorithm in patients who are at low risk for aortic dissection but for whom the diagnosis cannot be ruled out. The ADD-RS has a scoring range of 0 to 3; patients can be given just 1 point for each category (predisposing conditions, pain features, and exam findings). Thus, the score does not account for a patient who meets multiple criteria within a category. Patients meeting multiple criteria in a given category may not be appropriate candidates for the algorithm.

Evidence Appraisal

In 2010, the American Heart Association and the American College of Cardiology released guidelines for the diagnosis and management of AAS, including a set of 12 clinical markers of the disease. Rogers et al (2011) used retrospective data from the International Registry of Acute Aortic Dissection to validate the

sensitivity of these markers. Among 2538 patients with acute aortic dissection, 2430 patients (95.7%) were identified by 1 or more of the 12 proposed clinical risk markers.

The International Registry of Acute Aortic Dissection investigators (Suzuki 2009) also performed a prospective multicenter study of 220 patients with initial suspicion for acute aortic dissection. Eighty-seven of those patients were ultimately diagnosed with acute aortic dissection. The widely used D-dimer cutoff of <500 ng/mL showed promise for ruling out AAS, with a negative likelihood ratio of 0.07 through the first 24 hours and a sensitivity of 96.6%.

The authors of the ADvISED trial (Nazerian 2018) designed and tested the ADD-RS/D-dimer novel clinical pathway for ruling out acute aortic dissection, combining clinical risk stratification with D-dimer as a serum biomarker. This multicenter prospective observational trial enrolled 1850 consecutive chest pain patients, 241 (13%) of whom were diagnosed with AAS. An ADD-RS score of ≤ 1 and a negative D-dimer result demonstrated a sensitivity of 98.8%, a negative predictive value of 99.7%, and a negative likelihood ratio of 0.02. The shortcomings of this study included the following:

- Patients could receive only 1 point per category (eg, a patient with a new aortic insufficiency murmur, a focal neuro deficit, and no other high risk features would still be given just 1 point).
- The criteria for entry into the study were determined by the clinician.
- As with all of the studies described here, the prevalence of AAS found in this study was considerably higher than in previous studies. It is unclear how AAD-RS and D-dimer will perform in lower-risk groups.
